Abstract

AIM: To evaluate the influence of an intravitreal injection of bevacizumab and fasudil on the retinal vascular endothelial growth factor (VEGF), tumor necrosis factor alpha (TNFα), and caspase 3 levels in a diabetic rabbit model.

METHODS: The study included 6 healthy rabbits (Group 1), 6 rabbits with experimentally induced diabetes mellitus (DM) (Group 2), 7 rabbits with experimentally induced DM to which intravitreal bevacizumab was administered (Group 3), and 7 rabbits with experimentally induced DM to which intravitreal fasudil was administered (Group 4). An intravitreal injection of 1.25mg/50L bevacizumab in the right eye of rabbits in Group 3 and an intravitreal injection of 0.0064mg/50L fasudil in the right eye of rabbits in Group 4 were administered on day 21 after the induction of DM. The studied eyes of the rabbits were enucleated three days after the intravitreal injection. The TNFα, VEGF, and caspase 3 levels were determined using the ELISA method.

RESULTS: There was a statistically significant difference in the VEGF and caspase 3 levels between groups (P<0.005 and P<0.013, respectively), but the TNFα level did not differ significantly between groups (P=0.792). It was found that VEGF levels were significantly lower in Group 1 and Group 3 than in Group 2 using the Mann–Whitney U test with the Bonferroni correction (P=0.004 for both comparison). There was no statistically significant difference between other groups with regard to VEGF levels (the P value ranged between 0.015 and 0.886). Although the P values of the caspase 3 levels were 0.015 for Group 1 and Group 4, 0.038 for Group 2 and Group 3, and 0.018 for Group 3 and Group 4, these P values remained above the threshold P value of 0.0083, which was the statistically significant level for post hoc tests.

CONCLUSION: An intravitreal injection of bevacizumab decreased both the VEGF level, which plays a role in angiogenesis, and the caspase 3 level, which plays a role in apoptosis. Although not as effective as bevacizumab, fasudil had a beneficial effect on the VEGF levels but significantly increased the caspase 3 levels.

INTRODUCTION

The growing prevalence of diabetic retinopathy, the common ocular complication of diabetes mellitus (DM), is a critical problem for global public health [1]. While visual acuity is not always affected in early stages, progression of the diabetic retinopathy leads to severe vision loss[2]. Vascular endothelial growth factor (VEGF) has been shown to play a major role in macular edema and retinal neovascularization[3]. Activation of the VEGF-receptor pathway triggers a network of signaling processes that promotes endothelial cell growth, migration, survival from preexisting vessels, differentiation, and mobilization of endothelial progenitor cells from the bone marrow into the peripheral circulation[4–5]. Furthermore, VEGF increases vessel permeability, leading to the deposition of proteins in the interstitium that facilitate the process of angiogenesis[6]. Bevacizumab is a complete full-length humanized antibody that binds to all subtypes of VEGF and is successfully used in tumor therapy as a systemic drug[7]. Recent studies have demonstrated the usefulness of an intravitreal injection of bevacizumab in the reduction of macular edema secondary to central retinal vein occlusion, vascular permeability, and proliferative diabetic retinopathy[8–9]. The Rho/Rho-associated protein kinase (ROCK) pathway promotes leukocyte adhesion to the microvasculature by

INTRODUCTION

The growing prevalence of diabetic retinopathy, the common ocular complication of diabetes mellitus (DM), is a critical problem for global public health [1]. While visual acuity is not always affected in early stages, progression of the diabetic retinopathy leads to severe vision loss[2]. Vascular endothelial growth factor (VEGF) has been shown to play a major role in macular edema and retinal neovascularization[3]. Activation of the VEGF-receptor pathway triggers a network of signaling processes that promotes endothelial cell growth, migration, survival from preexisting vessels, differentiation, and mobilization of endothelial progenitor cells from the bone marrow into the peripheral circulation[4–5]. Furthermore, VEGF increases vessel permeability, leading to the deposition of proteins in the interstitium that facilitate the process of angiogenesis[6]. Bevacizumab is a complete full-length humanized antibody that binds to all subtypes of VEGF and is successfully used in tumor therapy as a systemic drug[7]. Recent studies have demonstrated the usefulness of an intravitreal injection of bevacizumab in the reduction of macular edema secondary to central retinal vein occlusion, vascular permeability, and proliferative diabetic retinopathy[8–9]. The Rho/Rho-associated protein kinase (ROCK) pathway promotes leukocyte adhesion to the microvasculature by
affecting the expression and function of adhesion molecules, including intercellular adhesion molecules (ICAMs)-1 and integrins. Moreover, ROCK causes firm adhesion through the activation of ezrin, radixin, and moesin in endothelial cells, which jointly form the anchoring structures for leukocyte integrins. These findings suggest that the elevated activity of the Rho-ROCK pathway is involved in the pathogenesis of diabetic microvasculopathy mediated through leukocyte adhesion.

The specific Rho-kinase inhibitor fasudil is relatively safe and effective in cardiovascular disease. Fasudil prevent development of diabetic nephropathy in diabetic rats. The therapeutic potential of fasudil for ocular angiogenic diseases through the blockade not only of Rho-kinase signaling but also of extracellular signal-related kinase and Akt signaling is demonstrated in vitro study. Intravitreal fasudil protects the vascular endothelium by inhibiting neutrophil adhesion and reducing neutrophil-induced endothelial injury in diabetic rats.

During the acute stages of diabetes, retinal neuropathy symptoms, including retinal neuronal function disorder, increases in the apoptosis of retinal ganglion cells and caspase 3 activity, and abnormal metabolic changes in retinal glial cells, have been observed. VEGF is elevated in diabetic retinopathy and causes both proliferation and increased permeability in vascular endothelial cells. Tumor necrosis factor alpha (TNFα) is an important pro-inflammatory factor in retinal and central nervous system neurodegenerative diseases, such as diabetic retinopathy and Parkinson's disease.

We evaluated the effect of intravitreal bevacizumab and fasudil on retinal VEGF, TNFα, and caspase 3 levels in a diabetic rabbit model.

MATERIALS AND METHODS

Materials Thirty-six male albino New Zealand rabbits weighing 2.0-2.5 kg were included in the study. They were housed in a room held at 22 ±1°C and 66% ±3% humidity with a 24-hour light-dark cycle. They were handled in accordance with the ARVO statement for the Use of Animals in Ophthalmic and Vision Research. The study was carried out with approval from the Committee on the Ethics of Animal Experiments of Abant Izzet Baysal University.

Methods Animals were randomly assigned to the groups. Diabetes was induced by a single intraperitoneal injection of 150 mg/kg streptozotocin (Calbiochem, Massachusetts, USA) dissolved in freshly prepared citrate buffer (0.1 mol/L citrate and 0.2 mol/L sodium phosphate, pH 4.5) under intraperitoneal 50 mg/kg ketamine and 5 mg/kg xylazine anesthesia. Two days after the streptozotocin injection, streptozotocin-injected rabbits were considered diabetic when the fasting glucose level was found to be >145 mg/dL with an Accu-Chek Go (Roche, Basel, Switzerland) by puncturing the marginal vein of the rabbit’s ear. The fasting blood glucose level was monitored weekly. We excluded 9 rabbits from the study (2 rabbits died before the initiation of the study, 1 rabbit died after the day of streptozotocin injection, 5 rabbits did not become diabetic after the streptozotocin injection, and 1 diabetic rabbit had a normal blood glucose level during the follow-up period). The rabbits were divided into 4 groups. Group 1 comprised 6 untreated, healthy rabbits; Group 2 comprised 6 diabetic rabbits; Group 3 comprised 7 diabetic rabbits treated with single intravitreal bevacizumab injection (1.25 mg/50 μL); and Group 4 comprised 7 diabetic rabbits treated with single intravitreal fasudil injection [0.0064 mg (180 μmol/L)/50 μL], which was dissolved with intraocular irrigating solution (Bausch & Lomb, Waterford, Ireland).

Bevacizumab and fasudil were purchased from Roche Pharma AG (Basel, Switzerland) and Calbiochem (Massachusetts, USA), respectively. The diabetic rabbits were kept under diabetic conditions for 21d, after which intravitreal bevacizumab and intravitreal fasudil were injected over a period of 1 min intravitreally to rabbits in Group 3 and Group 4 with a sterile 30-gauge needle from 1 mm of the limbus. After 3d of single intravitreal injection, rabbits were sacrificed by an intraperitoneal injection of 200 mg/kg sodium pentobarbital. The eyes were enucleated, and the retina was dissected, and samples were prepared and stored according to the manufacturer’s instructions until the ELISA was performed. The VEGF and TNFα levels were estimated with kits from Cusabio Biotech Co., Ltd. (Wuhan, China), and the caspase 3 levels were estimated with a kit from BioVision Inc. (California, USA) according to the manufacturers’ instructions. We performed all measurements in duplicate, and the tissue sample concentration was calculated from a standard curve.

Statistical Analysis All values were expressed as the mean± standard deviation. The statistical analysis was performed using the Kruskal Wallis test and the Mann-Whitney U test, using the Bonferroni adjustment as the post hoc test. Differences were accepted as significant for P<0.05.

RESULTS

We did not encounter any clinically visible gross complication in any group due to diabetes or any intervention during the study. The blood glucose levels measured during the study are presented in Table 1. The levels of VEGF, TNFα, and caspase 3 in all groups are presented in the Figures (Figures 1-3).

There was a statistically significant difference between the groups for the VEGF levels (Table 2). The Mann-Whitney U test using the Bonferroni adjustment revealed significant differences between Group 1 and Group 2 and between Group 2 and Group 3 (the P values were 0.004 for both). The significance of the difference between Group 2 and Group 4 was 0.015, which was over the significance level of 0.0083 obtained by the Bonferroni adjustment. There was no statistically significant difference between the groups for the TNFα levels (Table 2). There was a statistically significant difference between the groups for the caspase 3 levels (Table 2). The Mann-Whitney U test using the Bonferroni adjustment...
did not reveal a significant difference between groups (the $P$ values were over 0.0083).

### DISCUSSION

Inflammation, angiogenesis, and apoptosis play a role in the development of diabetic retinopathy and its complications. VEGF, also known as vascular permeability factor, has been demonstrated to increase retinal vessel permeability and plays a critical role in the pathogenesis of diabetic retinopathy \[25\]. Because VEGF has been shown to play a major role in macular edema and retinal neovascularization, anti-VEGF treatments have been used for the treatment of diabetic retinopathy \[3\]. Bevacizumab is a complete full-length humanized antibody that binds to all subtypes of VEGF. Ma \textit{et al.} \[26\] reported that a single intravitreal injection of bevacizumab (25mg/mL) may be beneficial as a therapy for preventing retinal vascular endothelial cell growth in the eyes of diabetic rats. In the current study, VEGF level decreased nearly to control group level in diabetic eyes after a single intravitreal bevacizumab injection.

The ROCK pathway plays an important role in pathological vascular conditions. The ROCK pathway promotes leukocyte adhesion to the microvasculature by affecting the expression

$^1$Kruskal Wallis test. TNF: Tumor necrosis factor; VEGF: Vascular endothelial growth factor.
and function of adhesion molecules. ROCK activation dephosphorylates endothelial nitric oxide synthase and decreases NO, which is an antiapoptotic factor.\textsuperscript{[27,28]} Fasudil is a potent ROCK inhibitor, and it has a therapeutic potential for lung cancer by inhibiting cell proliferation, migration, invasion, matrix metalloproteinase activity, and down-regulating the expression of RhoA and VEGF\textsuperscript{[30].} Kuno \textit{et al}.\textsuperscript{[31]} reported that fasudil inhibits TGF-beta-stimulated VEGF synthesis in osteoblast-like cell cultures. As a first study of intravitreal fasudil injection, Arita \textit{et al}.\textsuperscript{[32]} applied intravitreal fasudil injections after diabetes onset and reported that the ROCK pathway plays a critical role in diabetic retinal microvasculopathy.\textsuperscript{[32]} They repeated the fasudil injection every 3d after diabetes onset for 2 weeks due to the low half-life of fasudil. In the current study, we applied a single injection and studied the retinal parameters after 72h of injection. The VEGF level in the fasudil-injected group was lower than that in the diabetic group, but this difference was not statistically significant, most likely due to the small study group. The VEGF level of the fasudil-injected group was slightly higher than the VEGF levels of the control and bevacizumab-injected groups. Future studies are needed to determine the appropriate intravitreal dosage and form of fasudil due to the short half-life of fasudil and the limited number of studies.

TNFα contributes to the development of inflammation and the secretion of other cytokines. TNFα leads to the loss of retinal microvascular cells and plays a role in the early pathogenesis of diabetic retinopathy.\textsuperscript{[34]} The widespread distribution of TNFα and the nature of the adhesion molecules expressed by vascular endothelial cells in proliferative diabetic retinopathy membranes suggest that the local activation of TNFα and the enhanced expression of vascular cell adhesion molecules may play an important role in the development of the proliferative phase of diabetic retinopathy.\textsuperscript{[35]} TNFα and other inflammatory factors are expressed at significantly high levels under high glucose in human mesangial cells, and fasudil pretreatment decreases the TNFα secretion.\textsuperscript{[36]} We investigated the effects of bevacizumab and fasudil on retinal TNFα levels in an experimental diabetes model. We did not determine a significant difference between the groups. This was most likely due to the shorter study period in the current study; the duration was not long enough for the development of the neovascularization process.

Li \textit{et al}.\textsuperscript{[37]} reported that there is a significant increase in caspase 3 protein expression and that localization occurs in the nerve fiber layer, ganglion cell layer, and inner plexiform layer of the retina 2 weeks after the induction of diabetes. The intravitreal injection of 1.25mg of intravitreal bevacizumab does not result in structural changes in a porcine retina or changes in retinal caspase 3 levels.\textsuperscript{[38]} The ROCK inhibitor prevented hepatocyte damage in acute liver injury in rats and merits consideration as a hepatocyte-protective agent in liver injury, considering its direct antiapoptotic effect on hepatocytes \textit{in vitro} by decreasing caspase 3.\textsuperscript{[39]} In the current study, caspase 3 was significantly increased in the diabetic group. We determined that there was a significant difference in the caspase 3 levels of the groups ($P=0.013$). The caspase 3 level in the bevacizumab-applied group decreased nearly to control group levels, but the caspase 3 level in the fasudil-applied group exceeded the levels of caspase 3 in the diabetic group. According to the results of this study, we can propose that bevacizumab has an antiapoptotic effect but fasudil increases apoptosis at this dosage when applied as an intravitreal injection. Future studies investigating the dosage and application model of fasudil are needed.

There are some critical limitations to this study. This study was designed to investigate short-term changes. We induced an experimental diabetes model in rabbits using streptozotocin, which is not preferred in studies investigating long-term diabetes effects; in those studies, alloxan is frequently preferred. Alloxan produces severe diabetes; streptozotocin is less toxic, and the mortality rate of animals is lower for streptozotocin than for alloxan. Therapeutic and toxic dosages of intravitreal fasudil injections have not yet been determined. The dosage injected in the current study decreased the VEGF level but increased the caspase 3 level. Further research using test with higher specificities (Western blot), detecting apoptosis by other method (terminal deoxynucleotidyl transferase dUTP nick end labeling) and studying more cytokines (interleukins) are needed to elucidate the effect of intravitreal fasudil injection. Bevacizumab decreased VEGF and caspase 3 levels as a standard intravitreal agent. For the injected route and dosage, fasudil decreased VEGF levels but not as effectively as bevacizumab. However, fasudil increased the caspase 3 level, and this effect might alter either the dosages or injection route of fasudil. The ROCK pathway plays a role in the pathogenesis of diabetes, and applications of the ROCK inhibitor may play a potential therapeutic role in diabetic retinopathy. Future research is required to fully determine the presumed effect of fasudil on diabetic retinopathy.
